Has Google's much-celebrated flu estimator, **Google Flu Trends**, gotten a bit, shall we say, over-enthusiastic?

And so, how to perform better?

Precision public health? Hum...

“Precision” Public Health — Between Novelty and Hype

Merlin Chowkwanyun, M.P.H., Ph.D., Ronald Bayer, Ph.D., and Sandro Galea, M.D., Dr.P.H.

In May 2018, the National Institutes of Health (NIH) began enrollment for a vast medical research cohort. Named “All of Us,” it’s meant to include 1 million U.S. volunteers, who will be studied over 10 years at a cost of \$1.45 billion. The project promises to “lay the scientific foundation for a new era of personalized, highly effective health care,” a counterpoint to previous “‘one-size-fits-all’ medicine.”

All of Us derives from a decade’s worth of developments in the research world. In 2011, the National Academies of Sciences, Engineering, and Medicine called for a “new taxonomy of human disease,” stating that “opportunities to define diseases more precisely and to inform health-care decisions” were “being missed.”¹ Five years later, President Barack Obama launched the Precision Medicine Initiative. The concept was promoted by NIH Director Francis Collins, who defined it as “prevention and treatment strategies that take individual variability into account.”² A bandwagon effect followed, with marked shifts in resources and attention toward precision medicine.

The trend has now been ex-

tended to “precision public health” (PPH), which promises to reconfigure the mission of the public health field. Such a shift is not merely semantic. Substantial funding streams and institutional rewards are attached to all matters “precision,” with significant implications for approaches to population health. The Bill and Melinda Gates Foundation hosted a 2016 conference entitled “Precision Public Health: The First 1,000 Days,” which considered, among other things, infant mortality. Muin Khoury, head of the Office of Genomics and Public Health at the Centers for Disease Control and Prevention (CDC), declared 2016 the “year of precision public health.” Western Australia’s Office of Population Health Genomics, which first introduced the term, is cosponsoring an international conference on PPH in the coming months, as is the Rockefeller Foundation. PPH proponents argue that the public health field ignores at its peril emerging technologies that can fundamentally alter our understanding of who is vulnerable and who falls ill.

But there are key issues to consider before public health throws

its lot in with the precision agenda. What are the implications of this scientific and institutional turn for the future of public health? Does it offer the opportunity for a reconceptualized, empowered public health enterprise — or might it represent an abandonment of our mission of enhancing population well-being? And how novel is PPH, anyway?

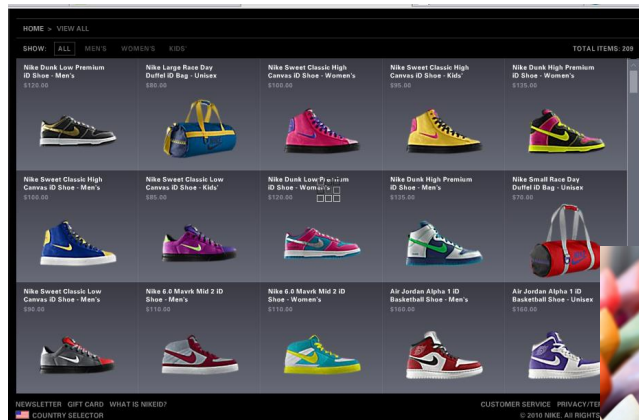

Beginning this conversation requires clarifying the divide between precision medicine and traditional public health analysis, policy, and practice. Precision medicine starts with the individual. Insofar as it considers groups that may be at increased risk for disease, vulnerability is conceptualized biologically, and particularly genomically. Improved population health follows from improved health of multiple individuals. In contrast, public health begins with populations. Increased vulnerability is framed as the consequence of structural factors, including social class, ethnic background, gender and sexual identity, and physical environment, among others. Many factors shaping the health of populations have no individual-level analogue but are properties of our shared surround-

Precision public health: why not?

Precision public health is about using the power of data to improve health and achieve social justice—equity, social inclusion, and empowerment. It should not be feared. It should be embraced.

interventions of all kinds to those most in need. Nothing in this definition excludes the traditional concerns of public health. On the contrary, precision public health emphasises the importance of those determinants for communities that have been invisibilised. The fact is that the power of data to transform what we understand about the health predicaments of communities has entered a new era. Two examples. Work from the Institute for Health Metrics and Evaluation, published last month, reviewed over 200 geographically detailed surveys and censuses on child mortality across 46 African countries. When under-5 mortality was estimated at a spatial resolution of 5 km×5 km pixels, a remarkable and disturbing picture emerged. Far from showing the

Context—the historical evolution of a country's health system, for example—matters. While digital tools offer tremendous opportunities, they cannot deliver their full value unless equal attention is paid to enlarging and improving the skills and capabilities of the health workforce. "Pilotitis"—a preoccupation with pilot projects that are ultimately unsustainable—must be avoided. Precision public health is about using the power of data to improve health and achieve social justice—equity, social inclusion, and empowerment. It should not be feared. It should be embraced.

Providing medical algorithms integrated in smartphone applications offers the opportunity **to rapidly detect and report** an increase in fever cases using a syndromic and etiological approach.

Augmented surveillance and detection of new outbreaks

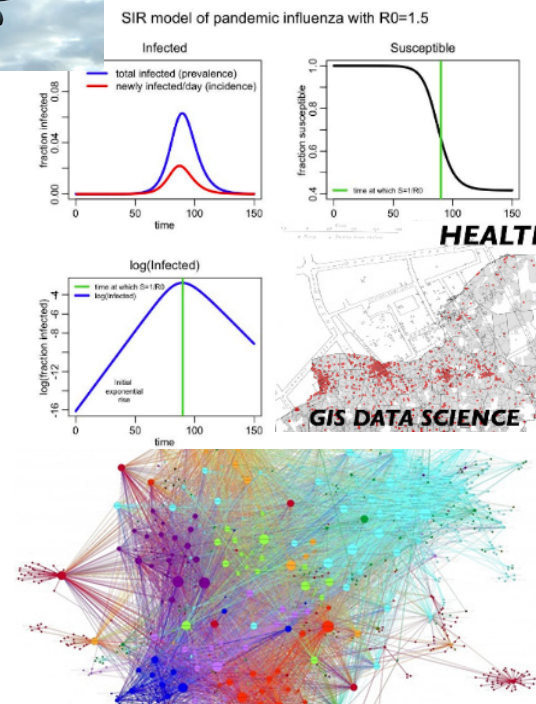

Along with these field data, **other data from diverse sources** including remote sensing data from satellites, social media and environmental can augment available information

Augmented surveillance and detection of new outbreaks

This data can be used to **inform epidemiological models**, GIS or to forecast new outbreaks and detect transmission networks through AI.

Early detection of outbreaks **guides intervention** efforts increasing capacity in relevant local clinical services and improving outcomes.

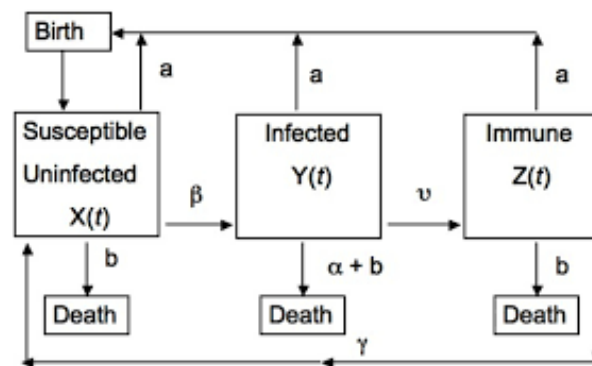

Develop tools for simplified **phylogenetic analyses** in the field

(Self-) forecasting in multiple networks

The origin and phylogenies of the various circulating viruses is often poorly understood, hence there is potentially high added value in the development of a **phylogenetic software package**, which uses data and samples collected remotely, helping to predict and respond to new epidemics

Spatio-temporal and individual-based **mathematical models**

Information on **pre-existing immunity profiles in the population** can help to adjust diagnostic algorithms and identify pitfalls in currently available diagnostics (such as cross-reactivity).
